Communication Optical Cable Architecture

Overview

Fiber Optics Fundamentals: SMF, MMF & Link BudgetA comprehensive understanding of fiber optic cable fundamentals is essential for engineers designing commu.

Key Takeaways

Communication optical cables consist of a core, cladding, protective coatings, strengthening members, and an outer sheath, each serving specific roles in signal transmission and mechanical protection.

Core

The core is the central part of the optical cable where light signals propagate. It is typically made of high-purity glass (silica) or sometimes plastic, and its diameter varies depending on the fiber type: around 9 µm for single-mode fibers and 50–62. 5 µm for multimode fibers.

The core's refractive index is higher than the surrounding cladding to enable total internal reflection, which confines light within the core for efficient transmission.

Cladding

Surrounding the core is the cladding, made of similar materials with a slightly lower refractive index. The cladding ensures that light remains within the core and prevents signal loss. It also provides a smooth interface for the core and contributes to the fiber's optical performance.

Coating and Buffer

The primary coating or buffer layer is a protective plastic layer applied over the cladding. It shields the fiber from mechanical damage, moisture, and microbending, which could degrade signal quality. Some cables include additional resin buffer layers or tubes to form the cable core, especially in multi-fiber assemblies.

Strengthening Members

Optical fibers are fragile, so strengthening members are added to withstand tensile forces. These can be placed centrally within the core (common in layer-twisted or skeleton-type cables) or around the periphery of the sheath (common in U. S. designs).

Materials used include aramid yarns, fiberglass rods, or steel wires, providing mechanical durability without affecting optical performance.

Sheath

The sheath is the outer protective layer, often consisting of an inner and outer sheath. It can be made of plastic, steel, or aluminum strips, sometimes bonded for semi-hermetic protection. The sheath protects the cable from environmental factors such as moisture, chemicals, and physical impact, ensuring long-term reliability.

Cable Core Structures

Communication optical cables may adopt different core structures depending on application: Layer-twisted type: fibers are twisted in layers, available as loose or tight sleeves. Skeleton (trough) type: fibers are arranged around a central skeleton. Belt type: fibers are held between protective belts.

Central beam tube type: fibers are placed in a central tube for high-density or outdoor applications.

Summary

In essence, a communication optical cable is a carefully engineered assembly where the core and cladding handle light transmission, the coating and buffer protect the fiber, strengthening members provide mechanical support, and the sheath ensures environmental protection. This combination allows optical cables to deliver high-speed, long-distance, and reliable data transmission in various environments.
