Fiber optic patch cord reverse insertion

Overview

Uniboot patch cable are now used as the fiber optic patch cord of choice for high-density connections in data centers.

Key Takeaways

Reverse insertion, or polarity reversal, allows a fiber optic patch cord to switch transmit (Tx) and receive (Rx) channels without replacing the cable, commonly using LC Uniboot or duplex patch cords.

What Reverse Insertion Means

Reverse insertion, also called polarity reversal, is the process of changing the fiber connections so that the transmit (Tx) and receive (Rx) channels are swapped. This is essential in duplex fiber networks to ensure proper communication between devices. Standard patch cords are typically A-B polarity (Tx to Rx), but some applications require A-A polarity (straight-through) to match network wiring standards.

Types of Patch Cords Supporting Reverse PolarityLC Uniboot Duplex Patch Cords: These cables have a single jacket carrying both fibers and feature connectors that allow polarity reversal without tools. They are widely used in high-density data centers to reduce cable bulk and simplify management. Reverse Polarity Uniboot Cables: Factory-configured as A-B polarity, they can be switched to A-A polarity by rotating the connector housing, enabling quick adaptation to network requirements.

How to Reverse Polarity on LC Uniboot Patch CordsHold the outer frame of the LC Uniboot connector carefully, avoiding contact with the ferrule end face to prevent contamination. Push out the lock on the connector cover. Open the shrapnel outward and rotate the connector housing.

Switch the polarities of fibers A and B. Reinstall the outer frame in sequence to secure the connector. This process allows the patch cord to maintain low insertion loss while changing polarity, making it suitable for high-density wiring environments.

Considerations and Best Practices

Insertion Loss: Properly reversed patch cords maintain low insertion loss, typically under 0. 4 dB for high-performance connectors. Avoid Contamination: Never touch the ferrule end face during reversal to prevent scratches or debris that could degrade signal quality.

Compatibility: Ensure the patch cord type matches the network standard (LC, SC, MPO) and the required polarity (A-B or A-A) before installation. Testing: After reversal, verify polarity and signal integrity using an OTDR or optical power meter to confirm correct Tx/Rx alignment. Reverse insertion is a practical solution for adapting fiber networks without replacing cables, especially in dense data center environments where LC Uniboot patch cords are preferred for their space-saving and polarity-switching capabilities.
