PortFast Access Switch Loop

Overview

PortFast is a Catalyst switch feature that allows a port to transition immediately to forwarding state without passing through listening and learning phases. It is configured on ports connected to end devices—hosts, servers, IP phones, printers—that cannot cause spanning tree loops. This chapter describes how to configure the PortFast, BPDU guard, BPDU filter, UplinkFast, and BackboneFast, and loop guard spanning tree enhancements on the Catalyst enterprise LAN switches. When port fast is enabled on an interface the interface whenever it detects a protocol up the event, the port skips the listening and learning spanning tree states and goes straight to. PortFast (edge port in RSTP) skips listening and learning phases, allowing hosts to reach the network in milliseconds instead of 30 seconds. In your case, if SW02 is the root of all Vlans and you interconnect 2 links between these switches with SW01 having PortFast enabled on all ports, SW01 may loop as it will have both. And does the port really revert to normal STP operations (LSN/LRN/FWD) as soon as it receives the first bpdu?

if so, it technically prevents data forwarding as soon as it receives the 1st bpdu until FWD is reached.

Without guardrails, there is a short risk window if someone connects an unmanaged switch or loop-causing bridge to a host-facing port. You can get temporary forwarding where you did not want it.

Solved: portfast and loop risk

A loop may be created when connecting multiple inter-switch links to the same neighbor or different neighbors. PortFast delays the opening of the port while Spanning-Tree calculates the best
