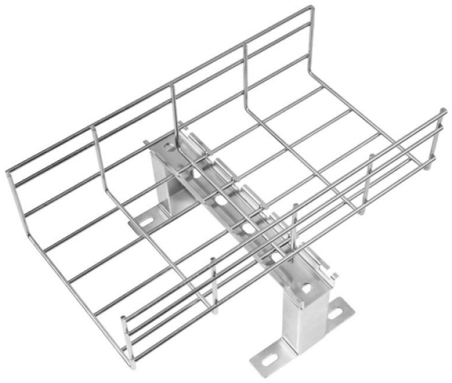
Switch optical interface bit error



Overview

Troubleshoot TC alarms on ATM switches with the same steps as on POS interfaces. Bit errors point to a physical layer problem between the ATM switch and other devices in the path.

Key Takeaways

Bit errors on a switch optical interface are often caused by faulty optical modules, mismatched fiber types, or low received optical power, and can be diagnosed by checking module status, optical power, and link integrity.

Common Causes of Bit Errors

Faulty Optical Module: Even if the transmit power is normal, a defective module can cause CRC errors and packet loss. Modules may fail due to manufacturing defects, aging, or environmental stress such as overheating. Fiber Issues: Bends, breaks, or high insertion loss in the fiber can reduce received optical power, leading to bit errors.

Contaminated connectors or improper termination can also degrade signal quality. Module and Fiber Type Mismatch: Single-mode modules must connect to single-mode fiber, and multimode modules to multimode fiber. Mismatched types prevent proper transmission and can generate errors.

Switch Port or Configuration Problems: Unsupported or incompatible transceivers may be rejected by the switch, causing the interface to enter an error-disabled state. Firmware or policy restrictions can also trigger bit errors.

Diagnostic Steps

Check Optical Power: Use commands like display interface transceiver verbose (Huawei) or equivalent on Cisco to verify transmit and receive optical power. Low receive power indicates fiber or module issues. Inspect Physical Connections: Ensure connectors are clean, properly seated, and free of damage.

Bypass patch panels if necessary to isolate the fault. Test with Known-Good Modules: Replace the optical module with a verified working module of the same type to determine if the original module is faulty. Verify Fiber Type and Distance: Confirm that the fiber type matches the module and that the link distance is within the module's specifications.

Check Switch Logs and Status: Look for error messages such as %PM-4-ERR_DISABLE: gbic-invalid or unsupported transceiver warnings. Use show interface or equivalent to check for CRC errors, packet loss, or errdisable status.

Preventive Measures

Use vendor-approved optical modules and verify compatibility with the switch. Maintain clean fiber connectors and avoid sharp bends in the fiber path. Monitor module temperature and optical power using Digital Diagnostic Monitoring (DDM) to detect early signs of failure.

Document any unsupported transceiver overrides to ensure network support and compliance. By systematically checking optical power, module integrity, fiber quality, and switch configuration, most bit errors on optical interfaces can be identified and resolved efficiently.
