What are some testing techniques for optical splitters

Overview

It outlines the basics of passive optical network infrastructure, describes the most common attenuation mechanisms in optical fibers and the testing methodology for measuring optical splitter performance.

Key Takeaways

Optical splitters can be quickly tested using optical power meters, OTDRs, and PON-specific testers to measure insertion loss, splitting ratio, and port performance. Key Testing Methods1.

Optical Power Meter and Light Source

Connect a calibrated light source to the splitter input and measure the output power at each port using an optical power meter. Calculate the insertion loss by comparing input and output power. Typical excess loss should be minimal, e.g., ≤0.

3 dB for PLC splitters. This method is fast and effective for field verification of splitter performance and identifying high-loss or faulty ports. 2.

OTD

R (Optical Time-Domain Reflectometer)Use an OTDR to detect reflection events and measure loss along each output fiber.

For PO

N splitters, a high-dynamic-range OTDR is recommended to accurately test through splitters with high loss (up to 15–17 dB for 1x32 splitters),.

OTD

R testing is particularly useful for identifying faults, fiber breaks, or misalignments without disconnecting the network. 3. PON-Specific TestersDevices like the VIAVI OLP-87/88 series or PON power meters allow testing from the subscriber side without disrupting other users.

These testers measure both downstream and upstream signals, verifying correct power levels and splitter functionality quickly.

Practical Tips for Quick Testing

Clean connectors thoroughly before testing to avoid high-loss readings caused by dust or debris. Check fiber alignment to ensure proper coupling into splitter ports. Misalignment can cause unstable or inconsistent readings.

Inspect for physical damage such as cracks or broken fibers, which can significantly affect performance. Sequential port testing: Measure each output port in sequence to quickly identify any outliers or faulty channels. Use dual-wavelength sources (1310/1550 nm) for comprehensive testing, especially in FTTH networks.

Standards and Accuracy

Follow IE

C 61300-3-2 for input/output power difference and IEC 61300-3-6 for OTDR reflectometry. Maintain controlled temperature (23°C ± 5°C) and humidity (
